

Due by 4:30pm on September 23, 2020

Read chapter 1 of the textbook (section 1.8 is optional).

Please write precise and concise answers. Your algorithm descriptions should use either clear, concise, and precise plain English or clear, concise, and precise pseudo-code that uses a style similar to the pseudo-code in your textbook. Submit your solutions to problems **1-4(a)** via [D2L](#) as a Word or PDF file or as scans/photos of legible handwritten notes. Submit your solutions to problems **4(b)-5** via [Kattis](#).

Since each recursive call is $n/2$ of the previous we know that this is $O(\log(n))$ by drawing out a recursive tree

4. Problem 13 page 51 in your textbook.

An inversion in an array $A[1 \dots n]$ is a pair of indices (i, j) such that $i < j$ and $A[i] > A[j]$. The number of inversions in an n -element array is between 0 (if the array is sorted) and $(n/2)$ (if the array is sorted backward). Describe and analyze an algorithm to count the number of inversions in an n -element array in $O(n \log n)$ time. [Hint: Modify mergesort.]

Basically do a mergesort but keep track of the number of times the sort needs to rearrange indexes
 Divide array in half and recursively run on left half and right half
 Keep halving until the base case of one element in the array
 Merge the left half and the right half
 While merging check if left index is greater than right, if it is increment a counter
 Return the counter from the merge step and add it together with all other recursive merge steps that were called

This is just a merge sort with an extra linear step of incrementing a counter so we know this is $O(n \log n)$

5. Week 2 problem *batmanacci* on [Kattis](#).

(a) Describe the solution for inputs N and K using a recursive formula or pseudo-code and analyze the running time of your algorithm

Since $[n]$ is $[n-1] + [n-2]$ we know if the length of k is greater than the length of $[n-2]$ then k is the $[k - \text{length}[n-2]]$ element in $[n-1]$
 We can recursively loop through this logic of shifting the string number and character index until we get the the base case where $k = \text{length of string}$

```
def batmanacci(string_number, character_index):
    if string_number == 1:
        return "N"
    elif string_number == 2:
        return "A"
    else:
        while string_number > 2:
            if character_index > fibNumbers[string_number - 2]:
                character_index -= fibNumbers[string_number - 2]
                string_number -= 1
            else:
                string_number -= 2
        return batmanacci(string_number, character_index)
```

(b) Implement your solution using your preferred language and submit your implementation via [Kattis](#).

6. [Optional] Week 2 problem *closestpairs2* on [Kattis](#). Submit your solution via [Kattis](#). NOTE: Unfortunately, the CPU time limit for this problem is very tight and penalizes slower executing languages... My Python solution got a "Time Limit Exceeded" error whereas a C++ solution passed even though they both used the same algorithm. So, either use a "fast language" like C++, C, Rust, ... or be willing to accept that the judge will reject your correct solution...
